

BRIEFING

STAT 01 EN

ENERGY AND ENVIRONMENT

BASIC STATISTICS, INDICATORS AND TRENDS

Summary

The tables provide with a few exceptions the same data/figures/graphs for all Member States and acceding and applicant countries in the field of energy and environment with a special focus on renewable energies. In some cases other countries and regions are included.

EUROSTAT (New Cronos) was used as source in the first instance. When, however, there was insufficient data from this source then the International Energy Agency (IEA), the European Environmental Agency, European Wind Energy Association (EWEA) and Global Wind Energy Council (GWEC) and a few other sources have been very useful alternatives. National statistics have not been used.

The collection and analysis were finished primo November 2006.

The briefing is done on a privat initiative taken by Peter Palinkas and Jens Dalsgaard

COMMENTS ON TABLES

All tables are easy to read and understand. Comments are restricted, only a short introduction is given.

- **Table 1** shows the population for EU, Acceding and Applicant countries; as well as the gross domestic product (GDP) total in EURO and in PPS, and per capita in PPS (Purchasing Power Standard). It also gives the final energy consumption (total, per capita and per million GDP (PPS)). There are major differences between the countries. Except for Croatia the GDP per capita is much higher in EU countries than in the Acceding and Applicant countries. CO₂ emissions per capita show a big variation within the EU - especially if CO₂ emissions to GDP (in PPS) are compared. CO₂ emissions per MIO GDP for EU15-countries are - in general - much lower than for the new Member States (indication of more energy efficiency in EU15). Final energy consumption tends to be higher in EU15 - thus reflecting the higher economic output (GDP); but in relation to GDP, final energy consumption is less in the EU15 - thus reflecting the higher energy efficiency in EU15 than in the new Member States.
- **Table 2:** Breaks down the primary energy production into total primary production and production from renewable energies. Also the self-sufficiency rate (indigenous production as percentage part of gross inland consumption) is shown in table 2. Final energy consumption is broken down into consumption of the respective sectors (industry, transport and households). In order to avoid a misinterpretation, one has to keep in mind that some countries (especially Luxembourg and Portugal), only have a very small indigenous production, which depends totally on renewable energies; but the self-sufficiency rate in the case of Luxembourg is only 1.6 %, Cyprus 3.9% and Portugal only 14.9 %. A self-sufficiency rate above 100 (Denmark with 154.4) are indicating that this country is net exporter. A major difference between the EU15 and the new Member States is the fact that the percentage part of the transport sector is - in general - higher in EU15.
- **Table 3** gives a breakdown of primary energy production by sources (solid fuels, gas, crude oil, nuclear and renewable).
- **Table 4** gives energy balances and indicators for the European Union in 1995 and 2004. Energy dependency has increased from 1995 to 2004, but the variation between Member States are big. Energy intensity measured as final energy consumption (kilogram of oil equivalent (kgoe)) per GDP (in 1000 EUR at 1995-prices) has improved from 1995 to 2004, however the data are in general much better for the EU15-countries than for the new Member States.
- **Table 5** gives a breakdown of final energy consumption by fuel (oil, coal, gas, electricity/heat and renewable) for different years (1980, 1990, 2000 and 2004). Figures indicate that the percentage part of renewable energies for EU15 have increase from 2.3 % in 1980 to 3.7 % in 2004.
- **Table 6 and figure 1:** The development between 1995 and 2004 in GDP, final energy consumption, total and intensity is analysed. The overall performance in energy efficiency has been improved, however it got worse in 2004. The improvement over the period was not sufficient, however, to avoid an increase in total energy consumption.

- **Table 7** gives a short overview concerning primary energy production from renewable sources in 2004. It appears that the major part of renewable energies stems from biomass and waste (roughly two thirds of total energy production comes from renewables). Another element is hydro energy, whilst wind plays an important role in Denmark, Germany, Ireland, the Netherlands and Spain; solar energy is strongly utilised in Cyprus and Greece, and Italy makes good use of geothermal energy.
- **Table 8 and figure 2** illustrate the trend in primary energy production from renewable sources for the EU25.
- **Table 9 and 10.** Gross production of electrical energy is broken down by sources (hydro, geothermal electrical energy and wind energy) for EU in 1994, 1999 and 2004 (in GWh and as % of total Gross generation of electrical energy).
- **Table 11 and figure 3** give for EU25 the trend (1990-2004) of gross generation of electrical energy by source.
- **Table 12** gives a short summary concerning gross renewable electric energy generation as a percentage part of total gross generation of electrical energy for the periods 1994, 1999 and 2004. The renewable generation is broken down by sources. The figures are to some extent misleading: Luxembourg for example, does not have a real indigenous energy production, but some hydro power, which in 2004 contributed to 87.4 % of the total gross production of electrical energy (see also table 3 and table 2); in the case of Luxembourg the self-sufficiency rate is only 1.6 %; thus, the small indigenous hydro production leads to a high percentage part of gross production of electrical energy or primary energy production.
- **Table 13 and figure 4** illustrate for the European Union, Member States, acceding and applicant countries renewable as % of total gross energy generation and as % of final energy consumption for the year 2004.
- **Table 14** reveals the important part of biomass as part of primary energy production (see also table 7, where total primary energy production from renewable sources was broken down into biomass, hydro wind, solar and geothermal). For EU15 biomass presents a high percentage part (8.3 % in 2004) of total primary energy production and for EU25 8.1%.
- **Table 15** gives a short summary concerning total gross inland energy consumption and total primary energy production by region (World, EU, NAFTA, US, Central and Eastern Europe, CIS and Baltic, Russia, Africa, Middle East, China, Japan, and Latin America). **Table 15** reveals the differences between regions concerning total primary energy supply and total energy production.
- **Table 16 and figure 5** gives a short overview for different regions in the world concerning CO₂-emissions and other greenhouse gas emissions of the energy sector. Of particular interest is the difference between the regions, especially if CO₂ emissions are calculated per capita (f.ex. US 19.679 kg of CO₂/capita in 2003, whereas the world figure is only 3.986 kg/capita and Africa is only reaching 897 kg/capita). Recently i.e. 2000-2003 the most unfavourable development has been in Brazil, China and India with a growth as high as 20.1%. In the same period the increase has been 0.4% in USA, 4.5% in the EU25, see **figure 5**.

- **Table 17** compares important energy indicators for regions and individual countries. Measured on the energy efficiency (as total primary energy supply/gross domestic products) the European Union is doing very well. When it comes to CO₂/GDP the European Union is also doing well. Measured on both these indicators Russia and the Middle East are doing extremely badly.

- **Table 18** analyses the trend in the greenhouse gas in the European Union, Member States and USA and Japan in relation to the Kyoto protocol targets. The EU-15 has a GHG emissions reduction target of -8% over 1990 levels with national targets set under a burden sharing agreement. The New Member States are not part of this. The total emissions in 2004 were 0.9% lower than the base year 1990. Germany - the largest emitter - has reduced the emissions by 17.5%, whilst Spain has increased the emissions by 47.9%. Eleven of the 25 Member States were in 2004 below the Kyoto Protocol targets. In the EU25 CH₄ emissions account for 10.4% in 1990 and 7.9% in 2004, whilst N₂ accounts for 9.2% in 1990 and 8.1% in 2004.

- **Figure 6** shows the GHG in 2000-2004 for EU-15, EU-25, USA and Japan indexed on base year = 100. For comparison the emissions relative to 2008-2012 Kyoto Protocol targets are included.

- **Table 19** gives a short overview concerning emissions in EU25 by sectors in the period 1990-2003. During this period total CO₂ emissions were reduced by 5.5%. Except for the transport sector CO₂ emissions were reduced for all sectors.

- **Table 20 and figure 8** confirm the close correlation between economic activity and energy consumption. Assuming an economic growth of average 2% until 2030 would increase gross inland energy consumption by 80% to 3.150 million tons of oil equivalent from 1.747 million in 2004.

- **Table 21** shows the actual and forecast figures of installed wind energy capacity. The global wind energy capacity will be able to grow - according to forecast by Global Wind Energy Council (GWEC) - substantially from 2004 to 2010 (from 59.1 MW in 2005 to 160.000 MW in 2010). **Table 21** gives also a regional breakdown as far as installed wind energy capacity is concerned. The countries with most wind power capacity are Germany - by far the largest, with just over 18,428 MW - followed by USA, Spain, Denmark and India. Compared to population Denmark is leading by far with 576.9 watts/capita followed by Spain (233.0) and Germany (223.4). For EU15 the gross electricity generation from wind has increased from 4.067 GWh in 1995 to 68.278 in 2005. Germany saw for the third year a setback installing 1.799 megawatt in 2005. Spain installed 1.764 megawatt in 2005, i.e. 300 megawatt less than in 2004.

- **Figures 10 to 13** (page 31) show - focusing on wind energy - for EU15, Denmark, Germany and Spain the development of gross production of electrical energy by renewable sources (period 1991-2004).

- **Table 22 and figures 14 and 15** give the World Reserves of crude oil and natural gas. Crude oil reserves are concentrated at the Middle East. The concentration of natural gas to a specific region is less significant. 26.6% of the reserves are in Russia.

- **Table 23 and figure 16**. Crude oil reserves, production and demand by countries and country groups are compared.

- **Table 24 and figure 17** give on regional level similar information as **table 23/figure 15**.

- **Table 25 and figure 18** illustrate the dependency on imported energy from oil. Especially the level for Japan is high - all oil is imported.
- **Table 26 and figure 19** show the refinery output by countries/region for the period 1971-2005.
- **Figure 20.** Inter-regional flows (mb/d) appear in this figure
- **Figure 21** illustrates the flow of oil out of the Middle East and North Africa (MENA) in 2004 and forecasts for 2030 according to various scenarios.
- **Figure 22 and figure 23** deal with the flow of gas. **Figure 22** shows the forecasted flow out of Middle East and North Africa in 2010 and 2030, whilst **figure 23** shows inter-regional flow in 2004 and forecast for 2030.
- **Table 27** shows for the European Union (EU25) the economic burden of the imports of energy.
- **Table 28.** For major energy exporting countries the importance of energy has been analysed.
- **Figure 24, 25 and 26** show the development of selected oil prices for certain time periods (1st January 1998-24th October 2006 (**figure 23**), monthly from January 1988-August 2006 (**figure 24**) and annually 1977-2005 (**figure 25**)).
- **Table 29 and figure 27** 88% of coal reserves are equally distributed between Asia/Oceania, Eastern Europe/Former U.S.S.R. and North America. 4% of the reserves are in the European Union (EU27).
- World hydropower potential is illustrated in **figure 28**.

Fig 9: Installed wind capacity (MW): Global and EU

Sources: European Wind Energy Association (EWEA)

Long-term Research and Development needs for wind energy for the time frame 2000 to 2020, IEA

World Energy Outlook 2004, IEA

Wind Force 12, EWEA

Renewables information 2006, IEA

Electricity Information 2006, IEA

American Wind Energy Association (AWEA)

Global Wind Energy Council (GWEC)

<http://windpower-monthly.com/WPM:WINDICATOR:942753>

(1) AWEA estimates that at least 6% of US electricity by 2020 can be produced by wind

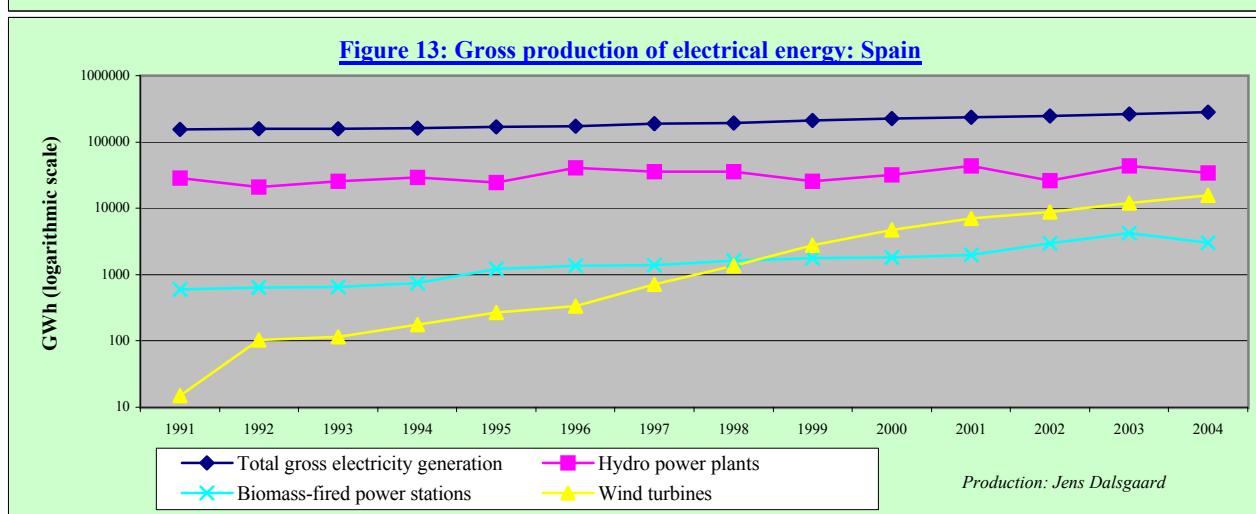

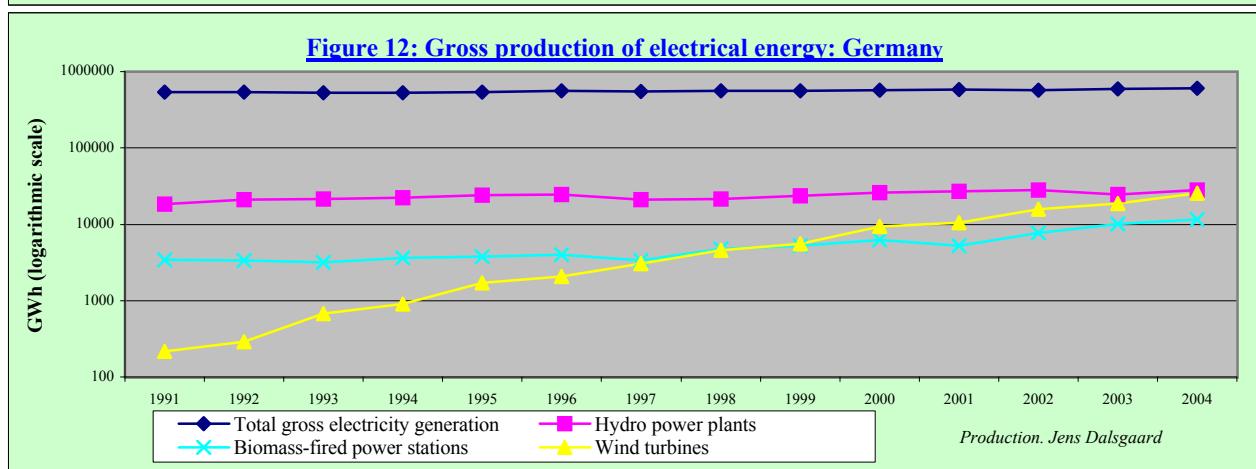

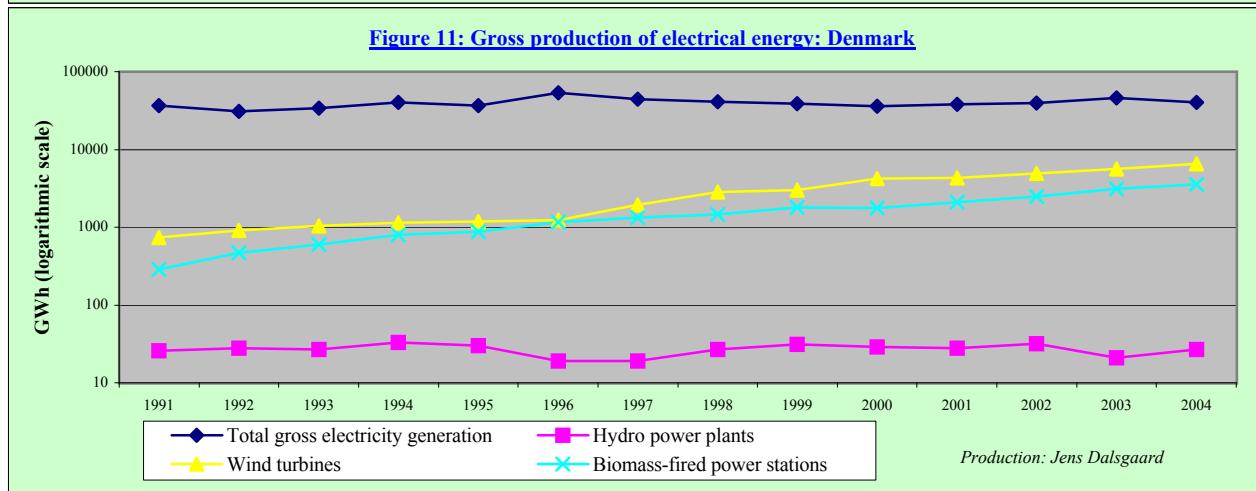

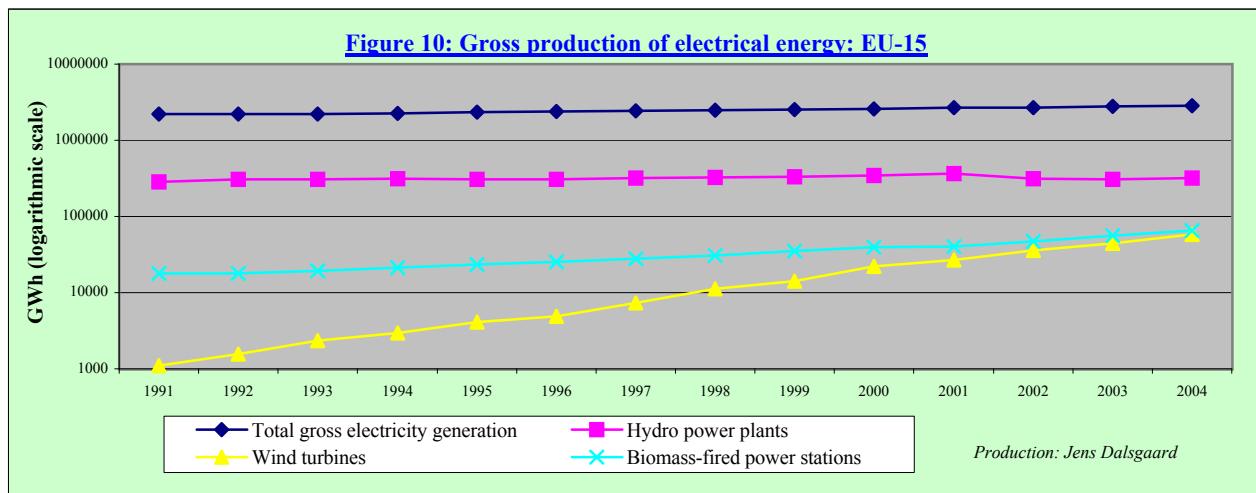

*EU15 target by 2010 (82.000 megawatt) includes 7.000 megawatt added (Summer 2005) as new target for Spain. For further info please see: http://www.ewea.org/06projects_events/proj_WEfacts.htm

**Capacity factor is the % of energy actually captured relative to what would be captured if the wind turbines were operating at full capacity all the time.

Production: Jens Dalsgaard

Figures written in *italic* are provisional/estimated

Remark: Analysis by the EWEA (see report Wind Force 12: A blueprint to achieve 12% of the world's electricity from wind power by 2020 (<http://www.ewea.org/03publications/WindForce12.htm>)) shows that there are no technical, economic, or resource limitations for wind power to supply 12% of the world's electricity by 2020. With stronger political commitments worldwide, the wind energy industry could install an estimated 230.000 MW by 2010 and 1.200.000 MW by 2020, which would give a production capacity of 3.100 TWh/year. Corresponding to a global wind power penetration of 12%. The annual reduction in CO2 would be 1832 million tons.
